## Description

[0001] The present invention provides a testing device and a method of its use, in particular for distinguishing between hydrocarbons.

5 [0002] There are many occasions when liquids are to be mixed commercially on a large scale and/or frequently, in particular distillate liquid products in a refinery or derived from a refinery, and it is essential that the correct liquids are mixed. Examples of such mixing occurs during transfer of fresh product e.g. gasolines or kerosenes to replenish tanks containing previously made product, as well as the dispensing of propulsion fuel e.g. motor gasoline or aviation gasoline, marine fuels, jet fuel or diesel into tanks of appropriate vehicles e.g. cars, lorries or piston or jet aircraft. The consequences of misfuelling are at best a nuisance and at worst lethal in the case of aircraft. In particular it is essential to be able to distinguish easily between aviation gasoline and jet fuel, or between motor gasoline and diesel. Existing methods involve use of a number of different techniques e.g. different colours and labels, audible warnings, and different nozzle sizes.

10 [0003] USP 5225679A describes determining the properties of liquid fuels e.g. octane level via analysis of the components of the fuel. USP 5330073A describes controlling the dispensing of liquid hydrocarbons by means of a sensor near the dispenser and is directed to controlling leaks; the sensor involves an optical waveguide which contacts the liquid fuel and can activate an automatic cut off.

[0004] A device and method have now been found to achieve the distinction quickly, easily and routinely.

15 [0005] The present invention provides a method for controlling the movement of a liquid preferably comprising a liquid hydrocarbon from a first location to a second location, via closure means capable reversibly of moving at least partly (and preferably completely) between an open and a closed position, at least one of said first and second locations having a vapour space, and preferably at least one of the first and second locations having a vapour space above the liquid, which process comprises analyzing the vapour in one or both locations, comparing the results of the analysis (es) with a standard or each other, and using the results of the comparison to control the movement of the closure means. Preferably the first location has vapour space above the liquid and the second location has vapour space, optionally above a liquid, and the process especially comprises analyzing the vapour in or from the second location and optionally in or from the first location comparing the results of the analysis in or from the second location, with a standard or the results from the analysis in or from the first location.

20 [0006] The invention also provides an apparatus for controllable passage of a liquid which comprises a first zone containing said liquid, a reversible closure means, a first line between said first zone and said closure means, a second zone defining a vapour space for vapour of said liquid and optionally also said liquid, a second line from said closure means to or into said second zone, at least one detector for analyzing vapour in or from said second zone and/or above liquid in said first or second zones, means for transmitting the data from said detector(s) to processing means for comparing said data from one of said zones with a pre-set level or with data from the other of said zones, means for controlling movement of enclosure means, operation of said processing means and said controlling means being dependant on said comparison.

25 [0007] The present invention also provides a modification of said apparatus in which said second line passes into said second zone but is not integral with it and said detector is inside or preferably outside said second line and analyzes the vapour from said second zone. In this case the second line preferably has mounted on or in it said detector, and may be reversibly inserted into said second zone and the vapour analyzed. The second line provides the line for transporting the liquid as well as a support for the detector.

30 [0008] The present invention also provides an apparatus for dispensing a liquid e.g. a hydrocarbon such as a fuel which comprises a nozzle for inserting into a tank containing vapour e.g. a fuel tank, a reversible closure means preferably valve in said nozzle or in a feed line thereto for control of dispensing of liquid e.g. fuel, a detector for contacting the vapour from or in the tank, e.g. for insertion into said vapour, said detector being preferably capable of being in vapour contact with the dispensing end of said nozzle, means for passing a signal from said detector to a processing means for comparison of said signal, and a controller receiving output from said comparison for controlling movement of the liquid e.g. fuel, e.g. allowing or stopping its movement, preferably using said valve.

35 [0009] The invention will be described with respect to differentiating between fuels, but is applicable to other liquids as described below.

40 [0010] The movement of the liquid from the first zone to the second may be from a tank, a bulk one such as a non movable one e.g. an underground fuel tank via a fuel dispenser e.g. nozzle or bowser into a tank of a movable vehicle e.g. one powered by a combustion engine, as at a gasoline or rail car filling station, or an aircraft or boat, ship or tanker refuelling point or cargo loading point. The first zone may also be in a tank or pipe and the second zone a tank, e.g. for passing fresh gasoline feed components or blended gasoline to fill a partly full tank of previously made material, for example in a tank farm or from a fuel tanker into the pipes and tank of a filling station or from a tank on land and pipes into a ship tank. The first zone may also be in a tank and the second in a pipe, leading elsewhere in a refinery e.g. moving gasoline from a tank to a second location for subsequent blending. The first and second zones may also

be in refinery pipes. In the case of pipes, there may be head space above the liquid level in which vapour is present and can be analyzed. The tanks are usually storage vessels for the liquid, either stationary as in underground or above ground repositories for fuel, especially ones periodically filled with fuel, e.g. from sea, rail or road tankers or fed directly by pipeline e.g. in/or from a refinery, or moveable in transport vehicles for propelling them e.g. in cars, lorries or boats for containing them e.g. in gasoline road rail or sea tankers. Thus the tanks may be storage vessels or containers for long or short term retention of fuel.

**[0011]** The liquid being moved into the second location is one whose vapour is different from that of a liquid which it is not desired to be present in the second location e.g. because they are incompatible with each other or more usually because of the unsuitability of the undesired liquid in that second location. An Example of the latter is when the second location is a fuel tank for powering a combustion engine, for which one or more liquid fuels cannot or should not be used.

**[0012]** The liquid being moved preferably comprises a hydrocarbon which is liquid at 25°C e.g. fuel, lubricant or crude oil containing partly volatile hydrocarbons, e.g. of 4-20 such as 4-10 carbons and usually aliphatic or aromatic, and possibly also non-hydrocarbon components, such as oxygen compounds e.g. ether octane boosters or phenols, or antioxidants, nitrogen compounds such as inhibitors/dispersants or cetane improvers such as organo nitrates and/or sulphur compounds e.g. impurities in the fuel, and/or perfumes and/or octane boosters e.g. organo leads.

**[0013]** The apparatus and method can also be used to distinguish between hydrocarbon liquids e.g. different types of crude oils, different kinds of gasolines e.g. leaded/unleaded or super unleaded fuels (with non lead octane boosters) or oxygenated/non oxygenated fuels, e.g. ones containing oxygen such as ethers e.g. MTBE, ETBE or TAME or alcohols, or feedstocks therefor e.g. reformat, alkylate etc. middle distillate fuels e.g. kerosene, diesel and fuel oils or bunker fuels such as marine fuel, heating and electricity generating oils. Other examples are the distinction between high sulphur diesel oil (e.g. a residual fuel) and low sulphur diesel oil e.g. a middle distillate, the diesel oils containing more or less than 0.05% of sulphur containing compounds (expressed by weight as sulphur). Diesels of nominally the same grade e.g. cetane number but containing different compounds may be differentiated. Further examples involve distinction between gasoline, e.g. motor gasoline, paraffin (or gas oil) diesel and heating oil, e.g. in an agricultural environment; the order from gasoline to heating oil is the order of decreasing volatility. Distinction between hydrocarbon fuels e.g. diesel and biofuels e.g. esters of long chain acids e.g. rape seed oil can also be made. Other examples in the petroleum industry are differentiating between lube oils e.g. synthetic and by hydrocarbon oils, and between heat transfer oils. Further examples of liquids are different types of solvents or reactants used in chemical, petrochemical or pharmaceutical industries.

**[0014]** The liquid to be moved may be liquid at 25°C, either under atmospheric pressure, or under higher pressures e.g. a liquefied gas, such as liquid petroleum gas (LPG, predominantly butanes) and compressed natural gas (CNG, predominantly methane). Preferably liquefied gases are moved at reduced temperature e.g. -200°C to 0°C such as when the invention is used to distinguish between liquid nitrogen, liquid oxygen and/or liquid air, or between LPG and SNG. The liquid to be moved may be under a pressure less than atmospheric in order to increase its volatility and hence the sensitivity of the sensors. The liquid being moved may be at raised temperature e.g. 50-200°C, in order to decrease the viscosity or because its melting point is above 25°C, examples of this use are between bitumens or between petroleum waxes or other materials solid at 25°C but distinguishable from their vapours.

**[0015]** The invention may be aimed at ensuring that the vapour over the first zone is the same as in the second zone i.e. that the liquid passed into the second zone is the same as that previously present in the second zone. It is therefore important that the liquid does not flow, e.g. closure means remains closed, if the vapours are different or if the vapour in the second zone does not otherwise meet a particular standard or threshold. It is particularly important to stop the mixing of a liquid from the first zone with vapours of a different liquid in the second zone when the initial boiling points of the liquids under atmospheric pressure differ by more than 100°C especially more than 135°C, in particular when one of the 2 liquids is aviation gasoline, e.g. comprising isopentane or butane with iso octanes, and/or aromatics such as toluene, and the other is jet fuel comprising kerosene, or alternatively when one of the liquids is motor gasoline or a component thereof and the other is a diesel/gas oil/vacuum gas oil/fuel or bunker oil fraction. The invention is of particular value to enable distinction to be made between gasolines, and hydrocarbons with initial atmospheric boiling points of at least 140°C especially at least 170°C, or hydrocarbons having a boiling point of at least 250°C.

**[0016]** The movement is stopped by the closure means, which may be a valve, in which case any movement is otherwise impelled or propelled by gravity or a pump, or the closure means may itself comprise the pump, acting as valve and pump.

**[0017]** Alternatively the movement may be allowed by operation of closure means for liquid moving in a different line from a line between the first location and second location as with a flow diverter or closure of a valve in a recirculating liquid stream forcing the liquid to flow via a different route i.e. between the 2 locations. The movement may be stopped by the presence of an unopen closure means which has fail safe arrangement such that it cannot be opened at all unless another criterion is met e.g. an engine running to pull vacuum on the closure means allowing it to open if required as in a vacuum lock. The closure means e.g. valve may be in or near to the liquid dispenser e.g. the nozzle as is preferred, or upstream thereof and in contact therewith (e.g. in a separate housing from the dispenser); the closure

means may also be in or near the dispensing pump. The separate housing may also comprise processing means second signal passage means, controlling means and a second valve controlling movement of said liquid. Preferably the controlling means is activated before any liquid is passed, rather than allowing a small amount of liquid to pass before the controller checks it is the "correct" liquid. The control decision may be passed to the closure means to open or shut a valve or operate a relay or a pump, by pneumatic means or electromagnetic radiation e.g. radio, light, laser means, such as use of light down optical fibres. Preferably the closure means stops liquid flowing, unless it receives the "correct" instruction to open, rather than the reverse. If desired a decision that the liquid to be passed from the first to the second zone is the "wrong" liquid and therefore is stopped from flowing may activate an alarm e.g. an audible and/or optical warning.

**[0018]** The detector for analysing may be in a vapour space above a tank, or in an entry neck thereto or, in the case of a line, in its top or better in a small extension over the line with head space. If desired a sampling point may be present over a liquid line, into which sample zone a portion of liquid may be drawn (and hence vapour produced). The latter may be useful for safety purposes especially to seal off the sample and detector zone from the line.

**[0019]** In the analysis, the nature or total concentration of one or more vapour components may be obtained or both the concentration and nature of the vapour components may be found. The output signal from the analyzer is passed to the processor e.g. a mini computer usually by wire or radiation to process the data and instruct the valve what action if any to take. In relation to the former approach the total concentration may be obtained as a single signal e.g. from the second zone, and this may be compared either to a fixed reference point or a standard concentration or to the corresponding value for the vapour in the first zone. In the comparisons, compensation means may be included e.g. in the controller to correct for differences between the temperature of measurement e.g. in the second zone and the fixed reference point or standard or first zone. Thus at a temperature of measurement of 35°C, avgas vapour concentration for example would be high but so would the kerosene vapour concentration so compensation for this is usually desirable. A comparison may be made so that action is taken to open the valve/operate the pump when the signal is above a level of background noise, or above any chosen level e.g. 10% above base, or part way e.g. 25-75% between the level for the fuel in the first zone e.g. gasoline and that for a fuel which should not be present in the second zone e.g. diesel; thus a signal above say 50% between the levels would allow the gasoline to move while one less than 25% would stop the movement as it would show the presence of diesel in the second zone. Alternatively if diesel were in the first zone, signal from the second zone above the desired level e.g. due to gasoline would stop movement of the diesel. In a similar way if the amplitude of the signal from the first zone were within given tolerances the same as that from the second zone, the liquid could pass, but not otherwise.

**[0020]** The key when considering analysis for the total concentration of one or more vapour components is that the signal from the second zone should be above or below a threshold value in order to allow liquid to move, being above the threshold when the amplitude of the signal from the second zone for the desired liquid is above that of the non desired liquid, and below the threshold in the reverse case.

**[0021]** The invention is particularly applicable when frequent connections are made in dispensing of liquids, in particular when the dispensing can be from one of a number of tanks of different liquids, into a number of different second locations; an example of this is the feeding from a multicompartment tanker e.g. (road, rail or boat tanker) into a number of separate tanks e.g. at a filling station or the feeding from one or a number of different tanks into a number of different tanks e.g. of vehicles.

**[0022]** The analysis may be by nature of one or more of the components in the liquid to help distinguish more finely between liquids. In this case the detector (or detectors) provide more than 1 signal, which can provide a finger print or pattern characteristic of the liquid and special computer techniques e.g. chemometric analysis such as regression techniques e.g. Principal Component Analysis or Cluster Analysis or Neural network analysis can be used to compare the liquids. Again similar analysis within tolerances to standards or above fixed levels or comparison with other liquids would allow passage of the liquid. Preferably, however, only the total concentration of vapour is measured for ease of operation and simplicity. Thus when the analysis is of total vapour concentration or is specific to at least one compound present in said liquid, the comparison of the results of the analysis controls movement of the closure means depending on whether the total vapour concentration or the amount of said compound(s) present respectively is above or below a defined level.

**[0023]** The output from the processor is usually a go signal to instruct the controller to open the valve or allow it to open or activate the pump, or no signal or a no go signal to close the valve or not allow it to open. Once the signal has been passed any subsequent change in the concentration of vapour usually does not trigger a fresh signal. So a high concentration of vapour can trip a go signal but a subsequent reduction usually does not trip a no go signal; by this means once the vapour in the second zone has been "recognized" as correct, the flow of the liquid can be governed by any manually or remote operated valve without risk of the detector signal overriding it. The controller usually acts almost instantly e.g. whenever the sensor shows the "correct" liquid, but may have an in-built delay, which may be useful e.g. when scheduling blending operations for a refinery tank farm moving components to or from a tank. In this latter case the controller usually has a memory, a memorized reading from the sensor for comparison with a preset

level and a go/no-go logic. The closure means activatable by the controller may be upstream of the pump i.e. between tank and pump, as may be the case with a number of tanks separately feeding a single pump, but is preferably at or in proximity of the fuel dispenser. In the latter case the closure means may be separate from the dispenser and upstream, e.g. in the form of a separate fitting retro fittable between the dispenser and its feed line from the pump. The valve may otherwise be part of the dispenser (see below), or downstream of the dispenser e.g. in a sheath retrofittable with the entrance to the receiving tank, of a vehicle such as an aeroplane, car or boat (see below).

**[0024]** The benefit of the method is that it stops mis-fueling or mixing between liquids, usually of widely different boiling point and hence concentration of vapours therefrom. The control can be on line or at line.

**[0025]** In an embodiment of the method of the invention, the first location may have a vapour space optionally above the liquid, and there is a vapour space at the second location, which may or may not also be above a liquid and may or may not contain vapour. The vapour at the first location can be analyzed and compared to a standard, the standard being for the liquid desired to be moved to the second location; an example of this is the filling of empty clean tanks with a specified fuel from a store. The standard may have been preset or relate to the last vapour at the second location (e.g. with a time delay). The vapour at the second location can also be analyzed and compared to the standard, there being no vapour above liquid at the first location.

**[0026]** The overall apparatus can be integral with no relative movement of the parts apart from any movement of the closure means or movement due to use of flexible lines; an example of this is the transfer of fuel in integral lines from a first line or tank to another line or tank. The apparatus may also be non integral e.g. with relative movement of the second line and second zone. These may be releasably joined e.g. with clips, as in the case of dispensers for diesel or fuel oil temporarily joined to input lines for tanks on land, or in vehicles or on ships or for aviation fuels temporarily joined to input lines in aircraft. The second line and second zone may also not be joined, but moved in and out thereof. This is the case with a fuel nozzle removed from a holder e.g. in a fuel "pump" stand in a filling station and inserted into a fuel tank of a vehicle. The nozzle can carry the detector into the second zone.

**[0027]** The detector can also be mounted in or especially on an extra tube which can be temporarily joined to the nozzle e.g. as a sheath surrounding the nozzle end, which may be locked in place, or by a clip on the extra tube onto a corresponding flange on the nozzle or the reverse. The extra tube has in it a valve movable between open and shut position on instruction from a controller. The extra tube may also not be joined to the nozzle but may be separate from the tank but capable of being carried with the tank, or may be releasably or non releasably attached to the tank e.g. in its neck. The extra tube may be adapted to surround or be surrounded by any sieve present in the nozzle or entry to the tank, e.g. outside a frustoconical sieve, the valve being a flap in the bottom of the extra tube. In this way the detector may be associated with the tank providing the second location and hence be carried by the vehicle/aircraft/boat etc i.e. with the second zone, in which case the processor and controller may be similarly carried. A negative signal from the processor would ensure the valve remained shut. By this means, the vehicle/boat/plane etc carries with it all the equipment needed to stop entry of the "wrong" liquid, without having to rely on equipment in association with the fuel source i.e. the tank on land or in the filling or refuelling station. Such arrangements with the extra tube are easy to retrofit to existing systems.

**[0028]** If desired the extra tube may have a number of detectors each capable alternately of being brought into contact with the vapour, with means, e.g. externally mounted on the tube, of bringing each detector in line. Thus a rotatable disc externally carrying identification of each of the various vapours to which each detector is sensitive may be used to allow the vapour of the desired fuel feed to contact the appropriate detector. Thus dialing the appropriate fuel on the disc on the extra tube would give the user freedom to allow that fuel to fill the tank. This approach would be valuable where the nature of the fuel in the dispensing tank is unknown or not known with certainty, or one dispensing device is fed by more than one dispensing tank.

**[0029]** The apparatus may comprise a line passing from a first to a second location which are separated by a reversible closure means e.g. valve. A pump separate from the valve may be present in said line or upstream of the first location. The detector may be in the vapour space over the first or preferably the second zone or especially temporarily in the second zone i.e. near the end of the line inserted into said zone. The detector provides a signal(s) to the processor which passes a signal to a controller which activates the valve/pump. The signals may be sent by wire or fibre optics or by electromagnetic radiation, especially infra red, microwave or other radio waves. Advantageously where the fuel dispenser comprises a nozzle and fuel control valve, as well as a detector, the detector can pass the signal to a processor also comprised by the dispenser by wire or fibre optics or radiation, and hence to a controller for activating the valve. When the controller and pump or valve, or processor and controller are separated by a fuel conducting line, passage of a signal between them may be by wire line but is preferably by fibre optic line or electromagnetic radiation.

**[0030]** When the detector is only to be temporarily inserted into the second zone, the detector may be inside the second line, but preferably is outside the line but mounted on it, so it can detect the vapour of the second zone separately from any residual vapour from the second line. In this case the apparatus can comprise the second line comprising the nozzle with analyzer, together with a control valve activated from the analyzer results, a pump for pumping the liquid and a second valve e.g. manually operated for dispensing the fuel; the line from pump to the nozzle can be rigid

or flexible or articulated.

**[0031]** The present invention also provides a fuel dispenser which comprises a nozzle for exit of the liquid e.g. fuel, a conduit through the dispenser for the liquid e.g. fuel, a valve in said conduit urged to a closed position by urging means but releasably openable against said urging means, a manually operatable actuator to open said valve, a vapour detector comprised by said dispenser adapted to be in vapour contact with vapours at the exit end of said nozzle, means for passing the output from said detector to a data processor and means for controlling said valve from the output of said processor. In this form the dispenser itself has the control means capable of stopping flow of "incorrect" fuel rather than the control means being separate from the dispenser e.g. with the pump in the fuel stand in the filling station which would need also means for passing the signal output from the controller to the valve/pump back to stop the flow, e.g. along a wire associated with the line for fuel from pump to dispenser.

**[0032]** When the detector is not itself in or moved into the second zone, it is preferred to withdraw the vapour from the second zone to the detector. Thus especially in connection with movement of liquid from a non movable tank to a tank of a movable vehicle, the vapour in the second location is analyzed by withdrawing it past a detector associated with a dispenser for the liquid comprising a releasable valve, said dispenser being in a liquid line between the first and second location. The dispenser preferably has a nozzle, an internal liquid conduit a valve and a body portion and the detector is located in or on the nozzle, between the nozzle and body portion or in the body portion.

**[0033]** The dispenser usually has the detector in a protective housing, which in the case when the detector is inside the nozzle, may be open towards the outer dispensing end of the nozzle, and in the case of the detector inside the nozzle, the housing is preferably not open towards the inside of the nozzle. By this means the detector has reduced contact with liquid fuel rather than fuel vapour. Preferably the dispenser incorporates means for purging the detector of vapour after use e.g. by use of air or an inert gas after the dispensing of fuel has ceased and/or a liquid level detector to shut off flow of fuel when the level in the tank is sufficiently high or frothing occurs at the tank entrance. Such a liquid level detector may comprise a hollow narrow tube inside the nozzle separate from the fuel and extending from the dispensing end of the nozzle to its head end, where a conduit leads from that tube to a safety anti-tilt device causing fuel flow cut out, if the nozzle is on its side e.g. on the floor. This device may be a ball which moves in a restricted space between a location allowing free movement of vapour in the conduit to a location where the movement is stopped because the ball blocks an exit hole for vapour. The liquid detector has an automatic cut out releasing the valve to its closed position in the event of decreased air pressure in the hollow tube and conduit from the rise in liquid level due to overfilling or frothing. The vapour detector may be located inside the above narrow tube, or preferably in the housing of the safety device or automatic cut out. The signal leads from the vapour detector may pass to a processor and controller also in the dispenser e.g. in the housing, or may return to the pump fuel stand; preferably the signals are sent by electromagnetic radiation but may be sent via wires or optical fibres, which may extend longitudinally in or on the walls of the fuel line between dispenser and pump. The automatic cut out means usually comprises the narrow tube to the nozzle, the conduit, which often contains the anti tilt device, an enclosed chamber with an internally spring loaded diaphragm constituting one wall, the chamber operating into a further thin passage extending longitudinally in the dispenser, separate from the fuel, the passage leading to a fine tube ending in the throat of the valve seat, against which the dispenser valve is urged in its closed position. The cut out means operates by passage of the fuel through the throat on depression of the dispensing handle causing by a Venturi effect a reduced pressure in the fine tube which causes suction all the way through to the narrow tube in the nozzle; if the latter tube is open, the pressure drop in the line is small and air is freely drawn through from the narrow tube to the fine tube and into the throat. If the narrow tube is blocked e.g. by liquid in the case of frothing, the pressure is rapidly reduced causing the diaphragm to move inwards into the chamber. The movement causes movement of an external blocking pin or rods to which the diaphragm is externally attached, the pin or rods restraining movement of the dispenser valve back to its valve seat. Thus the sensor can be used to block the mechanism of the automatic cut out, resulting in cut out and valve closure. Thus the operation of the automatic cut out draws the vapour from nozzle end to the detector in the line of the cut out mechanism.

**[0034]** The sensor or processor may send the signal to the processor or controller respectively and hence the pump to activate or stop the pump, or engage/disengage a locking device on the manually operatable activator e.g. dispenser trigger or may send a signal to activate the valve in the dispenser itself. In the last case, the dispenser may, as described above, have already an automatic cut out, which is usually in the form of a pressure activated diaphragm or similar device, which on activation results in release of a spring resulting in closure of the valve. The sensor may send the signal to a processor controlling the activation of the diaphragm; thus the sensor signal may activate an induction coil causing a ball or rod e.g. in an anti tilt device to move and hence move the diaphragm. Alternatively the processor may activate a pump to open a sensor valve in the hollow liquid level detector tube. In this case the sensor may check the vapours from the tank and, if acceptable for the fuel to be fed through the valve and dispenser (e.g. both are jet fuel), then the sensor valve may open, allowing the manual operation of the dispenser in the usual way; if the sensor finds the wrong fuel in the tank compared to the input feed lines, then this sensor valve remains closed, thereby causing the automatic cut out to operate i.e. via the diaphragm to keep the dispenser operation blocked. In a third operation the processor noting a signal for the wrong fuel may cause creation of a pressure difference e.g. in the hollow liquid level

detector tube, thereby activating the cut out, and hence not allowing fuel flow; the pressure difference may be created by activation of a pump or other movement of air or operation of a flap or mini valve in the detector tube.

**[0035]** With some dispensers, the automatic cut out may not be needed for safety reasons, but a cut out mechanism comprising the hollow tube, housing for the cut out and diaphragm and associated springs etc. may be used instead for the analysis, location of sensor, and control of the invention. Hence, the hollow tube may lead to the housing, where the sensor is located, as well as or instead of the diaphragm. The activation by the sensor may result in movement of the diaphragm, overriding the manual operation of the flow valve. The diaphragm (and hence the valve) may be released by the safety device, automatic cut out and/or vapour detector.

**[0036]** In this latter embodiment of the dispenser the detector may be in a head portion of the dispenser e.g. in association with the diaphragm, such as to override and trip it. Advantageously however the detector is in a position in relation to the narrow liquid level detector tube upstream of the head portion of the dispenser, which comprises the valve and diaphragm. In this case the nozzle and head portion of the dispenser may be separated by a hollow boss or collar or annular chamber having a core for passage of the fuel and optionally a separate hollow tube or channel adapted to be located in relation to corresponding tubes or channels in the nozzle and in the head end. The boss, collar or chamber also comprises a detector e.g. one located in an enclosed chamber therein open to the tube or channel, as well as a processor taking a signal from and analyzing the results from the detector and for activating means to stop passage of the vapour in the tube of channel to the automatic cut out, e.g. a controller to act on instructions from the processor. In this way the detector and processor and stopping means may be in an annulus in the boss, chamber or collar, which is separate from but in use engageable with the nozzle and head portion. Such an approach makes easy retrofitting of the detector, processor and stopping means to an existing nozzle and head portion with automatic cut out. Usually if the dispenser has an automatic cut out the sensor will activate the cut out when the incorrect fuel is detected, but when the dispenser is not so fitted, then it usually will pass a signal by radiation electrical wire or fibre optics to the pump housing to stop passage of fuel.

**[0037]** The collar or chamber in the dispenser may be annular or toroidal in shape, and may optionally be reflective inside e.g. coated with reflective metal e.g. silver. The vapour passes into the chamber. Through it may be directed analyzing radiation from a source, going round the annulus and to a detector located upstream of the entry of the radiation, to give the radiation a long and relatively constant path length. The collar or annular chamber may have a perforated wall e.g. the outward facing end or diameter thereof; the vapour may then enter through a circumferential surface or an inward facing diameter pass through the device past the sensor and pass outside through the perforated face. A mechanical piston, activated directly or indirectly by movement of the nozzle into the tank, may effect aspiration of the vapour through the chamber, particularly when no automatic cut device is provided.

**[0038]** The dispenser may also comprise a sheath or bellows at least partly longitudinally surrounding the dispenser e.g. surrounding the nozzle down to its dispensing end; there may also be a means for sucking vapour past the handle end of the nozzle which means may be comprised by the dispenser or be distant therefrom e.g. back at the pump and connected to the dispenser by a line part of or attached to the fuel hose line. Such sheaths or bellows are used in vapour recovery systems. In this case the detector may be present between the sheath/bellows and the nozzle, e.g. mounted towards the handle end of the nozzle, rather than the dispensing end. The vapours from the second zone are thus withdrawn past the nozzle and analyzed there, rather than analyzed in the zone. Thus the sheath or bellows e.g. of flexible plastics material may be collapsible in the manner of a concertina about the nozzle but be close fitted to the dispenser body near the manual actuator on the lower side of the dispenser, and with a rigid walled channel on the upper side of the dispenser, the channel leading e.g. to suction means for vapour recovery. In the channel the sensor may be located to be acted upon by the vapour. The sheath or bellows may have a toroidal end with rigid material to reinforce it and/or weigh it down e.g. a ring or sections thereof of rigid plastic or plastic covered metal, and the sheath may be separated from the nozzle by one or more separators loosely surrounding the nozzle. In this way insertion of the nozzle into the tank collapses the sheath or bellows but allows an adequate seal to the body surrounding the tank e.g. the side of the vehicle. Alternatively the sheath or bellows may lead to a sensor within the annulus surrounding the nozzle, but not mounted on the upper side of the body of the dispenser. In this embodiment the sheath or bellows is a pendant skirt surrounding the nozzle and ending in the weighted or reinforced end. Above the collapsible skirt is a rigid sheath fixedly surrounding the nozzle and having therein the sensor e.g. in a toroidal or annular form, with inward or downward facing perforations to allow entry/exit of vapour, and optionally outward facing perforations to allow exit of vapour. The weighted part of the collapsible skirt may be attached to one or more rigid elements extending axially and internally, or especially externally, of the sheath to the rigid sheath, wherein it may operate mechanically an activator for the sensor e.g. generator or flap or window opener, or may be used to aid removal of vapour; in this latter approach the element may close over the outward facing perforations when the skirt is non collapsed (to help protect the sensor from the environment) but may be moved axially relative to the perforations so a slot or hole in the element may register with the perforations, thereby allowing exit of vapours.

**[0039]** Many forms of detector or analyzer device can be used to determine the total concentration of vapours and optionally their nature(s); the detectors or analyzers can usually detect amounts of more than 0.1 ppm preferably more

than 1 ppm of the vapours. Among suitable detectors are spectroscopic and gas chromatographic devices, and olfactory sensors (also called "electronic noses"). The device may be at the site of the pipe or tank etc, though for safety purposes the device may be separate from its detector or sampling head and joined thereto by an analysis line, either for the sample (i.e. for taking a sample of the vapours from the site) or for the signal (e.g. down an optical fibre line). The device can be activated, ready for use, by a prior action of the user, in particular the removal of the nozzle from its location in a fuel pump stand in a filling station, so that the removal will release a depressed arm starting the pump, as well as activate the device e.g. apply power thereto or warm it (if required), or open an optical shutter in a spectroscopic detector. The detector or analyzer device may be battery powered, the battery(ies) being recharged by induction on return of the nozzle and thus detector to the "pump" receiving location when waiting for use, or the device or battery may be attached to one or more solar cells e.g. mounted on the dispenser upper surface.

[0040] The detector or analyzer device when comprised by the dispenser may be primed ready for use by prior action of the user on the dispenser. This action may be by depression of a button on an exterior surface of the dispenser such as on its top or head portion or by depression of a spring loaded annular arm surrounding the nozzle and hinged to the distant side of the nozzle or by depression of a spring loaded arm provided with 2 leg portions extending on either side of the nozzle which are hinged to opposing sides of the nozzle, the depression resulting from contact with the tank fuel opening or by movement of the handle of the dispenser, against the urging means, depression or movement causing closure of a battery circuit for the device or generating a priming current for the device. In the case of the handle, the initial movement against the urging means may prime the device, which analyzes the vapour, passes a signal to the processor and hence to the controller and valve. With fast acting detectors the delay between depression of the handle and flow of fuel (assuming a "correct" fuel) would be negligible. Use of such a priming system could increase the lifetime of any battery or reduce its size or even avoid need for its use.

[0041] The dispenser may also comprise means for activating the sensor, which may be an elongate member e.g. arm which is moveable between a rest position when the dispenser is separate from a tank, and a closed position when the nozzle is inserted into a fuel tank and the dispenser urged into contact with the surround to the neck of the tank; the act of urging moves the activating means to the closed position. The activation means may operate a generator to power the sensor and/or processor/controller or charge a battery therefor, or may mechanically operate means to bring vapour and the sensor in contact, preferably by moving vapour to a stationary sensor, e.g. operating a piston to suck vapour past a sensor, or opening a cover over a sensor (either directly or indirectly) allowing vapour to contact the sensor, or moving a sensor into contact with the vapour. Thus an activation lever e.g. a depressable arm can be connected mechanically via levers pivotally to move a piston in a tube, the tube upstream of the piston being air and downstream of the piston being the vapour to be tested, and the piston is moved past a recess or side arm to the tube, in which recess or arm a sensor is located. As the arm is depressed, the levers move the piston which sucks vapour behind it and when the piston moves past the recess or side arm, the vapour is drawn in contact with the sensor. When the nozzle is removed from the tank the depressable arm returns to its rest position moving the piston and hence withdrawing the vapour from the sensor and the tube, thereby purging it to reduce contamination when the nozzle is used again.

[0042] The piston may also on its return move vapour out of the tube, e.g. when the tube has a one way entry valve to stop egress of vapour but allow entry and also separately a one way exit valve to allow exit of vapour but deny entry; by this means too the sensor zone may be purged of vapour.

[0043] The activation lever may also mechanically move a flap or uncover a window thereby revealing the sensor to the vapour; the window may be in a slatted component adapted to move with respect to its frame between a closed position covering the sensor and an open position uncovering the sensor. The frame itself may comprise slats, but with one or more of the holes in the slats revealing the sensor.

[0044] If desired the activator lever can be part of or an extension of the manually operated activator for the main dispenser valve. In this case squeezing the activator also moves the piston drawing vapour into contact with the sensor; the main dispenser valve in this arrangement is adapted not to be moved until after the piston has been moved, the vapour registered by the sensor, and its nature accepted.

[0045] Among the possible spectroscopic techniques are infra red (both mid and near IR), ultraviolet and fluorescence spectroscopy and nuclear magnetic resonance (NMR) included pulsed NMR. In each case the vapour passes into or through an open or closed sample cell, and a beam of the appropriate radiation is passed through it and all or part of the spectrum is taken optionally with the aid of refracting or reflecting means e.g. a mirror(s) or prism(s) to multiply increase the path length and arrange the source next to the detector. The IR technique can use a single diode detector or a single multi diode detector, optionally with a filter selective to allow only certain wavelengths through it from the sample onto the detector; the selective filter is particularly important with NIR/FTIR detectors. For distinguishing between aviation gasoline (avgas) and jet fuel AVTUR or AVCAT, IR absorptions at 5000-4800, 4000-4500 (or 4000-4400), 2850-2980, 1130-80, 970-1040 and 680-780 (700-800)  $\text{cm}^{-1}$  may be used, in both cases the Avgas giving the higher absorptions. Absorptions due to isopentane may specifically be sought to distinguish between Avgas which contains significant amounts of isopentane and jet fuel which does not. In the case of UV fluorescence spectroscopy, radiation

at a specific wavelength or wavelengths, e.g. 254, 313, 366, 546 nm may be used to excite fluorescence in the visible region, which is detected. Filters at e.g. 370, 420, 450 and/or 550 nm may also be used.

**[0046]** For use with micro-gas chromatography, the vapours can contact the micro-gas chromatography solid state sensor, e.g. a spiral column etched on a silica/glass wafer, which separates them, and then by means of a suitable detector e.g. an optical diode or polymer coated electrochemical detector e.g. polymer coated Group VIII metal such as Pt, determine the amounts of each component and an indication of its nature. The signals from the latter can be analyzed to determine the total amounts and, if on the "correct" side with respect to the threshold or otherwise within the tolerances, then the processor can instruct the controller to open the valve allowing flow to occur when required.

**[0047]** The detector can also be a solid state gas sensor, which is a device whose conductivity is changed in the presence of a gas. Further details of such sensors are described in Sensors and Actuators B Vol.8 1992 pp 1-11 by HV Schurmer et al the content of which is herein included by reference. The detector comprises a sensor for the vapour which may be gas permeable, a support e.g. a membrane therefor, a pair of electrodes on either side of the sensor, e.g. having a reference and sensing electrode, means for providing a voltage across the electrodes and means for detecting any change in the conductance of the sensor e.g. a voltmeter or ammeter. The device is used in association with a data processor to process the output from the sensor. The changes may be in the sensor itself or in a device in contact with the sensor (a pellister approach), such as in relation to a ion sensitive/selective layer on an electrically conducting wire or plate or quartz oscillator with a layer of organic sensor adsorbed thereon; swelling of the polymer causes changes in the oscillation frequency of the quartz oscillator, as in a quartz microbalance. Alternatively the quartz layer in the microbalance may be sensitive to the vapour or may be provided with an optionally organic coated metal layer sensitive to the vapour. Thus the quartz layer may have a coating of Group VIII or IB metal such as copper, nickel, gold or ruthenium, platinum, palladium or rhodium. The metal layer may have had an organic coating e.g. of an organic sulphur compound such as an aliphatic aromatic or araliphatic polar compound e.g. thiol such as one with 4-24 carbons such as 6-16 carbons, e.g. dodecylmercaptan, especially on gold, or an aliphatic N-heterocyclic polar compound e.g. imidazoline with 6-24 carbons in the aliphatic e.g. alkyl or alkenyl group such as oleyl imidazoline. The polar organic treated metal may be more sensitive to one fuel over another e.g. kerosene over avgas, while the untreated metal may have a reverse sensitivity. There may be one sensor per device, or an array of sensors e.g. 2-50, 20-40, 2-20 or 3-6 each sensitive to a different compound, thereby enable a "fingerprint" of the vapour to be obtained. While each sensor, or array, may have an associated processor and controller, if desired there may be a number of sensors, but only one processor and controller, the signals from the sensors being scanned and passed to the processor and controller e.g. via a multiplexer. There may be at least one processor per controller usually 1-3, preferably 1, except when a processor is present to provide compensation e.g. for temperature differences between an analysis zone and a standard or another analysis zone.

**[0048]** Solid state sensors e.g. polymer coated metal oxide sensors are commercially available and vary from ones with only one sensor, sold for analysis of and sensitive to gaseous 1-4 carbon alkanes, carbon monoxide or oxygen, or multimatrix ones with many different heads, each sensitive to a different material. It has been found that polymer coated metal oxide sensors sensitive to carbon monoxide and/or methane are sensitive to Avgas and jet fuel as well.

**[0049]** The sensor itself may be inorganic or organic, examples of the former being metal oxide semi conductors, metal oxides SFETS and electrochemical cells, and examples of the latter being conducting polymers, lipid coated wires and Acoustic Wave sensors e.g. operating at 50-500 MHz e.g. 200-300 MHz. Metal oxide semi conductors are usually based on zinc, tin or titanium oxides with a catalytic metal or rare earth metal associated with them e.g. impregnated thereon, for example platinum or palladium gates. Examples are zinc oxide single crystals with suitable metal; these are also known as Taguchi gas sensors. These work by interaction of the hydrocarbon vapour with air over the catalyst to cause changes in the semi conductivity of the oxide; this interaction happens when the catalyst is heated e.g. to 300-400°C by a thin film heater, which is adjacent the sensor, usually on the side distant from the vapour source. By using different catalyst metals and/or different temperatures, different sensors interact with different hydrocarbons to different extents. The act of removal of the fuel nozzle from its stand, which usually starts the fuel pump, can trigger heating the heater or powering the sensor. The metal oxide can be on a support e.g. an oxidized silicon wafer or on porous alumina. These metal oxide gas sensors are preferred for sensing the more volatile hydrocarbons e.g. gasoline over diesel and aviation gasoline over jet fuel.

**[0050]** The conductive polymers may be for example optionally substituted poly pyrroles with a variety of cations e.g. sodium, potassium or lithium, and optionally with pendant functional groups. The hydrocarbon vapours may cause the conductive polymer to swell and/or change its permeability to hydrocarbon vapours and/or interact with the conductive polymer to different extents e.g. with formation of ion pairs thereby changing the conductivity of the polymer e.g. polypyrrole to different extents. The polymers may be used as such as the sensor but are preferably supported on a porous support e.g. alumina, or on a membrane, in which case the membrane itself is also externally protected except for a small area for direct exposure to the vapours.

**[0051]** The output signal from the sensor may be a single one for comparison as explained, with the baseline or threshold or another measured signal. The signals from an array may be used to produce a pattern and then the

analysed by chemometric techniques for comparison with known patterns e.g. for gasoline or diesel and a decision on the similarity to the known pattern used to control the valve movement. Preferably a single sensor is used to give information so control is based simply on the total vapour concentration especially when the device is for filling tanks with a more volatile fuel e.g. avgas and stopping filling with a less volatile fuel e.g. kerosene. When the sensor is used to differentiate between vapours of 2 different materials, preferably at least two are used, one or more of higher sensitivity to one material and the other or others being of higher sensitivity to the other material. Sensing of one material being the "correct" one, would then require a positive signal from one sensor to which it is more sensitive and a negative signal from the less sensitive sensor. This arrangement significantly increases the safety margin for the device. Another way to increase the margin is to have a reserve sensor in place in case of problems with the main one.

**[0052]** The invention is illustrated in the enclosed drawings in which Fig. 1 represents a schematic diagram of the overall apparatus and Fig.2-8 represent partly schematic drawings partly in section of fuel dispensing nozzles of the invention.

**[0053]** Referring now to Fig. 1, a tank 1 containing liquid hydrocarbon 2 has a top surface 3 in which is a first detector 4. From tank 1 leads a first line 5 to a pump stand housing 6 e.g. as in a gasoline filling station. In stand housing 6 on line 5 is a pump 8 and a valve 7 movable between open and closed positions. If desired the pump 8 may also act as a valve instead of separate valve 7. From pump 8 leads a second line 9, usually in part flexible leading to a fuel dispenser or bowser 10, which comprises a manually controlled arm 32 and valve 11 and a projecting nozzle 12. On the upper outside surface 13 of the end of the nozzle 12 is a second detector 14 located in a protective housing (see Fig.2 for further detail). The nozzle 12 is shown inserted with the neck 15 of the fuel tank 16 of a vehicle e.g. a car, which contains some liquid hydrocarbon 17, above which is vapour, so that the detector 14 is in the vapour.

**[0054]** First (20) and second (21) signal lines lead respectively from the first (4) and second (14) detectors back to the pumpstand housing 6 to a processor 22 which links with a controller 23 in the housing, itself linked via line 24 to control operation of the valve 7 or pump 8. Also shown is the receiving ledge 18 in housing 6 for dispenser 10, which when not in use depresses an arm 19. Alternatively instead of signal lines 20 and 21, the detectors may incorporate electromagnetic radiation generators and the processor 22 corresponding receivers.

**[0055]** When not in use, the dispenser 10 is received in ledge 18 thereby depressing arm 19. For use the dispenser 10 is removed from its ledge 18, releasing arm 19, which turns the power onto the pump 8 and/or can turn power onto the detector 14 or open an optical shutter. The nozzle 12 of the dispenser 10 is then inserted into the neck 15 of the fuel tank 16 of the vehicle. The second detector 14, activated by the power takes a measurement on the vapour in the tank 16, and sends a corresponding signal down line 21 to the processor 22, which compares it with the set threshold. If the signal meets the desired requirements so the vapour is acceptable, then processor 22 instructs controller 23 to open valve 7 or to start pump 8. Alternatively, (not shown) the release of arm 19 would not provide power to the pump 8, until the controller 23 instructed this, based on the instruction from the processor 22; in this case valve 7 may be omitted. Once the valve 7 or pump 8 are open and operating, then lines 5 and 9 are open so that on depression of the manual arm 32 in the dispenser 10 fuel is pumped from tank 1 through pump 8, dispenser 10, nozzle 12 and into tank 16. Once the manual arm 11 is released the flow stops, and the dispenser 10 is returned to its ledge 18 thereby depressing arm 19 and shutting off the pump 8, closing valve 7 (if present) and optionally turning off power to detector 14. The act of return to ledge 18 may trigger an inductive current to recharge the battery in the sensor.

**[0056]** In a modification of the above process, the decision to activate the valve 7/pump 8 is derived from a comparison of the signal from detector 14 in tank 16 with signal from detector 4 in tank 1, which is passed via signal line 20 to processor 22. If the signals have comparable amplitude (within given tolerances e.g.  $\pm 10\%$  of the signal), then the processor 22 will instruct the valve 7/pump 8 to open.

**[0057]** In either case if the vapour in tank 16 is different, so that the signal does not reach the threshold (e.g. when tank 1 contains gasoline and tank 16 diesel) or exceeds it (e.g. when the reverse is true), then the processor will reject the signals, and will not instruct the controller 23 to open the valve 7/pump 8. No liquid can then flow from tank 1 to tank 16, thereby obviating a potentially dangerous mis-fueling.

**[0058]** Referring now to Fig.2, which is a schematic partial cross section through a dispenser of this invention, the dispenser 10 has a nozzle 12 and a body part 30, in which is the control valve 11 held closed by urging means, not shown, but openable by mechanism 31 and manually depressable arm 32. Inside, and integral with or separate inside the nozzle 12 is an overflow cut out conduit 33, extending axially the length of the nozzle and then passing in a tube 34 across the fuel flow inside the body part 30 into a safety housing 35, which contains safety device 47 to shut off flow if the nozzle is tilted sideways and to shut off flow because of an induced vacuum in the conduit following entry of fuel into the conduit 33 due to overflow or frothing in the neck 15. Safety devices 47 comprise a diaphragm (64 see Fig.4) restrained from movement but whose movement when activated urges a rod to trip a spring loaded arm which closes valve 11, such safety devices are well known in the art and are shown schematically in outline in Fig.2. The detector 14 may be in the safety housing 35, the insertion of the nozzle 12 into the tank diffusing vapour from the tank up the safety conduit 33 and to the detector 14. Alternatively the detector may be located in the conduit 33 itself or in the nozzle in a separate conduit closed at its top end (36 shown dotted in Fig. 2), or on the outside of the nozzle 12,

e.g. on its upper surface 13 in a protective housing 37 (shown dotted in Fig.2). In each case of location of the detector 14, a signal line 21 and if required power lines (not shown) lead to the processor 22, in the pump housing 6, or, not shown, within the body part 30 or safety housing 35. In the latter cases, the controller 23 is also present in the body part 30 or housing 35, and similarly the line controlling opening/closure of the valve 11. If desired the signal lines can

5 be dispensed with and be replaced by electromagnetic radiation transmitters and receivers.  
**[0059]** Fig. 3 shows a modification of the dispenser of Fig.2 in which the nozzle 12 and body 10 of the dispenser are separated by an annular collar 40, whose central core is threaded either to engage with corresponding threads on nozzle 12, which may be of different dimensions for different fuels, and/or a tube 41 extending from body part 30. Collar 40 has an annulus 48 which is open via passage 42 to the threaded portion of nozzle 12 to overflow cut out conduit  
 10 33, which leads to outlet 71 in the body part 30 and is open for insertion in the neck 15 of tank 16. The annulus 48 is also open via passage way 43 through the transverse wall 44 of the collar 40 to an elongate channel 45 through the upper surface of body part 30. In channel 45 lies a ball 59 capable of free movement therein but capable of blocking the device 47 end of channel 45. In annulus 48 is located detector 14 with associated processor 22 (not shown) and controller 23 (not shown), and signal or radiation transmitters/receivers (not shown), as well as a valve 46 or other  
 15 closure device activatable by controller 23 to move between open and closed positions across passageway 43. Valve 46 may be replaced by any means for creating a pressure difference in passageway 43. Valve 11 has a nose 57 located in a seating surface 56, into which leads a thin channel 71 passing into a longitudinal passageway 36 leading to housing 35. Passage of fuel past seating surface 56 causes suction in channel 71 and hence to conduit 33. Upstream of nose 57 in the line of liquid inlet flow through body 10 is a flow controller 93 with a downstream conical face defining with a seating 94 a conical annular fluid channel 95.  
 20

**[0060]** In use of the dispenser of Fig.3, insertion of nozzle 12 into the neck of the fuel tank 16 forces vapour from above the tank 16 up conduit 33, and via passage 42 into annulus 48 where it contacts detector 14, which passes a signal to processor 22. If the processor 22 confirms that the vapour is of the correct fuel, then it passes a signal to controller 23 to open flap or valve 46 (or maintain flap open), thereby allowing vapour to reach the safety device 47 in  
 25 its housing 35. Manually squeezing arm 32 moves valve 11 to move away from seating surface 56 allowing fuel to pass through body 30 and out through nozzle 12 and into tank 16. However, if processor 22 finds that the vapour is of the incorrect fuel, then a signal is passed to controller 23 which activates flap or valve 46 to shut it (or keep it shut), thereby stopping air from reaching safety device 47, this stoppage causes a slight suction in elongate channel 45 thereby activating safety device 47 which stops further opening of valve 11. No fuel can then flow.

30 **[0061]** In the Fig.2 and 3 devices, preferably the processor 22 compares the results from detector 14 with an internal standard, preset for the fuel in tank 1. By this means transmission of signals significant distances is avoided, thereby aiding miniaturisation. If desired annulus 48 may have an axial length substantially greater e.g. more than 3 times greater than its transverse width, rather than of substantially similar dimensions.

**[0062]** Detector 14 and associated processor 22 and controller 23 may be sealed in annulus 48, but if desired collar 40 may be in two parts or have an access flap (not shown) to allow their replacement or adjustment.

35 **[0063]** Fig. 4 shows an embodiment of the dispenser of the invention. Body 10 has fuel tube 30 leading to valve 11 and nozzle 12. Arm 32 co-operates with mechanism 31 shown as a bifurcated body 50 and projecting lug 51. Arm 32 is pivotally mounted on body 10 by pin 92. Body 50 has a central slot 52 in which core 53 of valve 11 is free to move. Compression spring 54 constitutes urging means urging core 53 and hence valve 11 away from bearing surface 55  
 40 and towards a frusto-conical seating surface 56. Conical nose 57 is at the end of valve 11 distant from surface 55 and sealingly engaged by seating surface 56. Between nozzle 12 and nose 57 lies a neck 49 and a fuel passage 60 defined by walls 41 and passing axially through collar 40. Walls 41 separate passage 60 from an annulus 48 in collar 40. A passage 42 leads from annulus 48 to overflow cut out conduit 33 which leads inside down nozzle 12, to its end. Annulus 48 surrounds passage 60 and contains detector 14, processor 22, controller 23 and to which is electrically attached a generator 70. A depressable arm 61 has two extending legs 62 on either side of nozzle 12. The legs 62 are kept in place on collar 40 with an axle 63 passing through eyelets in each leg, and the arm is urged away from collar 40 by springs (not shown) acting on legs 62. Surrounding axle 63 is the generator 70. A flap or valve 46 is located at the exit from annulus 48 towards a safety passage 45 in the upper part of body 10 leading to a safety device 47. Safety device  
 45 47 comprises a spring loaded diaphragm 64 having a core 58 the distant end of which is located in a bar 65 which it restrains from movement. Bar 65 carries a lower ledge 66. One end of body 50 has a lip 68, which bears on ledge 66. Rod 65 is urged forwards towards nozzle 12 by spring 67. Handle 69 extends between safety device 47 and body 10. In safety passage 45 is a ball 59 free to move in a broadened section of passage 45 and able to allow air to move past the ball 59 except when the ball is at the end of the broadened section near to device 47. A thin channel 71 extends between neck 49 and device 47.  
 50

55 **[0064]** In use nozzle 12 is inserted into the neck of a tank containing liquid and residual vapour of a fuel; the insertion is such that arm 61 is depressed rapidly thereby causing generator 70 to produce electricity to power detector 14, processor 22, and controller 23 which are joined by wire lines. If desired not shown, generator 70 may be omitted, the power coming from an alternative source e.g. a battery and the depression of the arm 61 simply operating a switch

allowing the power to activate the detector etc. The act of insertion is also such as to direct vapour of the fuel along conduit 33 and into chamber 48 and also to ensure that the nozzle is inserted to a constant distance into the neck of the tank each time and hence to a similar vapour concentration. Detector 14 detects the vapour and passes a signal to processor 22 which determines, by reference to standards or otherwise, whether the fuel is the correct fuel, and instructs controller 23 to open or close flap or valve 46. If flap or valve 46 is closed, the passage of any fuel past neck 49 creates suction in tube 71 which triggers diaphragm 64 to move inwardly withdrawing core 58 and releasing rod 65, which moves forwards thereby causing lip 68 of bifurcated body 50 to move and allow valve 11 to be shut; no fuel can flow. If the "correct" fuel is sensed, pulling of arm 32 towards handle 69 causes lip 51 to bear on arm 31 which with ledge 66 on lip 68 pulls valve core 53 and hence opens valve 11 allowing fuel to flow.

**[0065]** Fig.5 shows a modification of the dispenser of Fig.3. Components comparable to those in Fig. 1-4 have been numbered the same and their location and role are not further described unless necessary. The dispenser of Fig.5 has surrounding nozzle 12 a skirt 72 which is flexible and collapsible having at its lower end a weighted ring (or sections of ring) 73 and at its upper end is attached to a rigid hollow frame 74 which surrounds the upper end of the nozzle and the head end of the body 30 of the dispenser up to a guard 96 for arm 32; the hollow frame 74 also extends over the top of body 30, where it becomes a rigid body with a vapour recovery conduit 75. Between nozzle 12 and safety device 47 on the top of body 30 in the region, where safety passage 45 is located, is mounted (by means not shown) a detection and control housing 76 which contains sensor 14 processor 22 and controller 23, joined by wires. Housing 76 is provided with a forward facing entry port 77, while sensor 14 has entry 78 and exit 79 orifices. Arm 32 is mounted on pivot 98 to act to pull valve 11.

**[0066]** In use the vapour recovery system e.g. operated from the pump 8 region pulls vapour into conduit 75 from skirt 72 and past housing 76. When the nozzle 12 is inserted in the tank of the vehicle to be fuelled, the skirt 72 collapses and vapour from the tank is drawn up past housing 76. Some vapour enters through port 77 and orifice 78 to sensor 14 where it is analyzed and the results passed to processor 22 and controller 23. Controller 23 can transmit a signal by radio or fibre optic cable (not shown) (e.g. along conduit 75) to instruct the pump 8. Alternatively controller 23 can act on ball 59 causing it to move; thus ball 59 may be of metal and the part of the body 30 above the ball may be of plastics material, so that an induced magnetic field from controller 23 can move ball 59 from a position from open to closure of channel 45. By the above means, if the sensor 14 detects the "correct" fuel vapour, fuel will flow continuously on depression of arm 32. If the sensor 14 detects the wrong vapour, controller 23 will cause the pump 8 to stop or channel 45 to block thereby creating suction in housing 35 and causing diaphragm 64 to move inwardly releasing valve 11 which closes; no fuel can flow.

**[0067]** Fig.6 is a modification of the dispenser of Fig. 4 of the invention, again like parts to those in Fig. 1-5 having like numbering. Fig.6 differs from Fig.4 in having no safety device 47 and its assorted related components and no annular chamber 40 for the sensor etc. However, Fig. 6 shows a detection control housing 76 mounted (by means not shown) on the body 30. Inside housing 76 are sensor 14, processor 22 and controller 23 jointed by wires. Sensor 14 is located off a shaft 80 in which moves a piston 81 under the influence of rod 82 and urged by movement of arm 97 against a return spring (not shown). A pivot 83 moves in arm 61 in an axial slot 84. Nose 57 of valve 11 is urged towards seating surface 56 by spring 54 while valve 11 is pivoted by pin 85 on arm 32.

**[0068]** In use of Fig.6 insertion of nozzle 12 into the tank depresses arm 61 causing piston 81 to move along shaft 80 past sensor 14, thereby drawing vapour from the tank onto sensor 14, which passes a signal to processor 22 and hence controller 23. If the signal shows an accepted fuel, pump 8 can operate so raising of arm 32 withdraws valve 11 and fuel flows down nozzle 12. If the fuel is "incorrect" controller 23 signals by radio or fibre optic link to the pump controller to block operation of the pump, so no fuel can flow.

**[0069]** Fig.7 is a modification still of Fig.6, there is no depressable arm 61 or piston to suck the vapour past the sensor 14. However the Fig.7 shows a skirt 72 around the nozzle as in Fig.5, and a toroidal collar 86 containing the sensor 14. The collar 86 has an internally reflecting surface and perforations 87 downwardly facing towards nozzle 12. Sensor 14 is joined to processor 22 by a wire. In use insertion of nozzle 12 into the tank collapses skirt 72 driving vapour upwards towards the perforations 87 and into the collar 86, where it is analyzed by sensor 14, the results passed to processor 22 and hence controller 23, from whence a signal is sent by radio or fibre optics to the pump, with subsequent operation or not as in Fig.6.

**[0070]** Fig.8 show a modification of the dispensers of Fig.3 and 5, but has no skirt, and the sensor 14 is in a different location. Surrounding the part of nozzle 12 nearest the head portion of body 30 is a toroidal collar 86 internally metallized and having downwardly facing perforations 87 towards the nozzle. Sensor 14 is inside collar 86 and signals from it pass by wire to processor 22 and controller 23. The conduit 33 is open via tube 34 to passage 45 and housing 35 and hence to thin tube 71, so in use the automatic cut operation represented by these features operates conventionally. The difference lies in the presence of collar 86 and housing 76 which can be retrofitted to an existing dispenser, Vapours from the tank enter the collar 86 by way of perforations 87, are sensed by sensor 14 and the results passed through to controller 23 as in the other Figures. Controller 23 can cause ball 59 to close the passage 45 or can signal to the pump.

**Example 1**

[0071] Samples of each of a Jet Fuel, which was DEF-STAN 91-91, NATO Code F35, Jet A1-AVTUR, and an Avgas, which was Aviation Gasoline 100LL/DEF-STAN 91-90, were poured into cans to half fill them with liquid, the remaining space being filled with vapour. An aspirator pipe was inserted into each vapour, and the gases which were aspirated, were passed into a 10 cm gas infra red spectrometer cell, where the spectrum of each was recorded. The results were as follows, with the main absorption regions being quoted.

Wavenumbers $\text{cm}^{-1}$ /Absorbances (times 1000)								
	5000	4800	4600	4440	4400	4350	4320	4270
Jet	2.5	2.6	2.8	2.9	3.1	3.5	3.5	3.5
Avgas	4.75	4.35	4.0	4.0	5.0	5.25	5.25	4.8

[0072] Thus analysis of an unknown at 5000-4800 or 4400-4270 especially 4390-4410, 4320-4350 or 4250-4300 especially 4270-8 $\text{cm}^{-1}$  shows from the size of the absorbance whether the unknown is avgas or jet fuel.

[0073] In the IR region of 3100-2800 $\text{cm}^{-1}$ , the results were as follows.

Wavenumbers $\text{cm}^{-1}$ /Absorbances								
	2980	2950	2940	2930	2920	2900	2880	2860
Jet	0.96	1.56	1.88	2.24	1.48	0.76	1.00	0.88
Avgas	1.28	1.16	0.90	0.76	0.70	0.60	0.64	0.24

[0074] Thus analysis of an unknown at 2930-40, or 2860-2880  $\text{cm}^{-1}$  shows whether the unknown is jet fuel or avgas.

[0075] In the IR region of 1300-900 $\text{cm}^{-1}$ , the results were as follows.

Wavenumbers $\text{cm}^{-1}$ /Absorbances (Times 1000)									
	1200	1175	1160	1150	1135	1035	1025	975	970
Jet	-4	-1	0	0	-1	-1	-1	0	0
Avgas	0	10	16	15	11	6.5	11	17.5	7.5

[0076] Thus analysis of the unknown at 1130-1180 especially 1140-1175, or 970-1040 e.g. 1025 or 975 $\text{cm}^{-1}$  shows whether the unknown is jet fuel or avgas.

[0077] The differences in absorption can thus be used to control a pump feeding jet fuel into aircraft by sampling the vapour in the aircraft fuel lines (via an aspirated suction line to the spectrometer), noting the size of the absorption at one of those absorptions detailed above and controlling activation of the pump or opening of a valve allowing fuel to pass into the aircraft fuel lines and hence tank depending on whether the absorption is above or below an appropriate value at that wavenumber. Thus in the above tests, with absorptions above 0.0035 at 4400-5000 $\text{cm}^{-1}$  or 0.0042 at 4250 to 4450 $\text{cm}^{-1}$  or 0.005 at 1125-1180 $\text{cm}^{-1}$  or 0.004 at 970-1040 $\text{cm}^{-1}$  a pump feeding jet fuel would be stopped, while a reading above 1.2 at 2920-2940 $\text{cm}^{-1}$  would activate the pump or open the valve allowing jet fuel into the fuel lines and tank. In practical operation, the instruments would be calibrated before use.

**Example 2**

[0078] The samples of liquid and vapour for the Avgas and Jet Fuel of Ex. 1 and also for another jet fuel, diesel oil and motor gasoline, were prepared as in Ex. 1, and the vapours aspirated past a commercially available electronic gas sensor GM1 Gas Surveyor 412 electronic sensor, sensitive to the detection of methane in air (from Gas Measurements Instruments, Renfrew Scotland); the sensor had a polymer coating on a metal oxide base, and had been sold for detecting hydrocarbons of 1-4 carbons, carbon monoxide and oxygen. The vapours were tested 2 mm into the necks of the cans.

[0079] The readings for the vapours of jet fuel (whether AVTUR or AVCAT) and avgas were <1 and >100 respectively while those for the vapours of diesel oil and motor gasoline were <1 and >100 respectively.

[0080] In the same way as in Example 1, the sensor can be used to control a pump feeding jet fuel to an aircraft fuel tank, by sampling the vapour in the tank or in the tank neck as above and controlling the pump depending on whether

the reading is above or below a specific reading, in this specific test 40-70, i.e. activating the pump or opening the valve if the reading is below 40-70 corresponding to jet fuel in the tank. Likewise if measurement is made in the tank or tank neck and jet fuel would be fed by the pump and the reading is above 40-70, then the tank clearly contains avgas and the pump would not be started and/or the valve would be at closed.

### Example 3

[0081] Samples of vapours from jet fuel and avgas were kept in separate containers, and the vapours aspirated past a multimatrix polymer coated metal oxide sensors A32S, commercially available from AROMASCAN plc, Crewe, England. The sensor has different polymer coatings in the 32 matrix heads. The results were analysed by Neural Analysis in a 5 point scan. The results were expressed on a 2-dimensional Principle Components Analysis Graph, which showed that the weighted average of the 5 results from each kind of vapour differed significantly, the average value of (PCA1) along the abscissa (x axis) for the avgas being significantly larger than that for jet fuel. Thus the sensors can be used in the same way as in Ex. 2.

### Example 4

[0082] The method of Ex. 2 was repeated with the vapours tested 2cm above the can mouth and also in the vapour in the cans.

The results were as follows.

Readings		
	Above Can mouth	In Can
Jet Fuel	1	11
Avgas	16	>100

### Example 5

[0083] The method of Ex. 1 was repeated with a stream of dry nitrogen blown over the fuel in a container and into the IR gas cell. The spectral results at 4000-4500  $\text{cm}^{-1}$  were as follows.

Wavenumbers $\text{cm}^{-1}$ /Absorbance (X 1000)						
	4050	4100	4200	4300	4350	4400
Jet	0	0	0	0	0	0
Avgas	4	5	3.6	6	8.4	6

Thus measurement at 4050-4450  $\text{cm}^{-1}$  differentiates between avgas and jet fuel. The results at 700-800  $\text{cm}^{-1}$  were as follows:

Wavenumbers $\text{cm}^{-1}$ /Absorbances				
	700	730	740	750
Jet	0.16	0.4	0.2	0.1
Avgas	0	0.04	0	0

Measurement at 700-750  $\text{cm}^{-1}$  differentiates between avgas and jet fuel, the latter giving the higher absorptions. The spectral differences between the avgas and jet fuel can be used to control the flow of fuel as described in Ex. 1.

### Example 6

[0084] The method of Ex. 1 was repeated with vapours from diesel fuel and motor gasoline, (Mogas), in this case unleaded gasoline of MON 84.6 and RON 96.2. The absorptions in the 4500-4000  $\text{cm}^{-1}$  region were as follows:

Wavenumbers cm <sup>-1</sup> /Absorbances X 10 <sup>3</sup>					
	4430	4400	4300	4250	4040
Mogas	30	48	52	45	30
Diesel	7	7	8	8	6

Hence absorptions in the region 4040-4420 cm<sup>-1</sup> differentiate between the mogas and diesel.  
The results in the 600-80 cm<sup>-1</sup> region were as follows:

Wavenumbers cm <sup>-1</sup> /Absorbance				
	770	750	725	700
Mogas	0	0	0.04	0
Diesel	0.1	0.1	0.4	0.16

Absorptions at 680-770 cm<sup>-1</sup> differentiate.

In the field e.g. on a gasoline filling station or airport filling point, the spectra would be contaminated with absorptions from carbon dioxide and water, whose spectra at 5530-5100, 4000-3350, 2100-1300 and less than 500 cm<sup>-1</sup> would if required need to be subtracted from the spectra of the fuels.

#### Example 7

**[0085]** Two quartz crystal microbalances were used, one (A) with a vacuum deposited gold layer on the oscillating quartz crystal and the other (B) with the vacuum deposited gold layer pretreated with organic solution of dodecylmercaptan in toluene for 12hr followed by evaporation of solvent. Each microbalance had the planar quartz crystal bonded on either side to a conductor, which were joined in an oscillator circuit, set to oscillate at a frequency of 10 MHz. Changes in frequency on immersion of the microbalance into the vapour above 10ml of fuel in a 20ml vessel were noted. The fuels were avgas and jet fuel used in the earlier Examples. The results were as follows.

**[0086]** Balance (A). Avgas change 80Hz, jet fuel change 190Hz. In a different location for the balance Avgas change 60Hz, jet fuel change 120Hz.

**[0087]** Balance (B). Avgas change 400Hz, jet fuel change 700Hz. With these balances as detectors mounted on a dispenser nozzle as shown in the accompanying drawings one can control fueling and avoid misfuelling of an aircraft with avgas or jet fuel.

#### Claims

1. A method for controlling the movement of a liquid, from a first location (1) to a second location (16) via closure means capable reversibly of moving at least partly between an open and a closed position, at least one of the first and second locations having a vapour space, which method comprises analyzing the vapour in one or both locations, comparing the results of the analysis(es) with a standard or each other and using the results of the comparison to control the movement of the closure means.
2. A method according to claim 1, wherein the first and second locations have a vapour space.
3. A method according to claim 1 or 2 wherein the liquid being moved is not gasoline or light oil.
4. A method according to any one of the preceding claims wherein the first location has the vapour space above the liquid, the second location has vapour space, the method comprising analyzing the vapour in or from the second location and optionally in or from the first location, and comparing the results of the analysis in or from the second location with a standard or with the results from the analysis in or from the first location.
5. A method according to any one of the preceding claims wherein the liquid comprises a liquid hydrocarbon and at least one of said first and second locations has a vapour space above a liquid.

6. A method according to Claim 4 or 5, wherein the vapour in each of the first and second locations is independently selected from:
  - (a) aviation gasoline and kerosene, or
  - (b) motor gasoline and diesel oil or
  - (c) leaded gasoline and unleaded gasoline.
7. A method according to any one of the preceding claims wherein the analysis is of total vapour concentration and the comparison of the results of the analysis controls movement of the closure means depending on whether the total vapour concentration is above or below a defined level.
8. A method according to any one of claims 1-6 wherein the analysis is specific to at least one compound present in said liquid and the comparison of the results of the analysis controls movement of the closure means depending on whether the amount of said compound (s) present is above or below a defined level.
9. A method according to any one of the preceding claims wherein the first location is a non-movable tank (1) of liquid and the second location is a tank (16) of a movable vehicle.
10. A method according to claim 9 which comprises analyzing the vapour in the second location (16) by withdrawing it past a detector (14) associated with a dispenser (10) for the liquid comprising a releasable valve (11), said dispenser being in a liquid line (5, 9) between the first and second location.
11. A method according to claim 10 wherein the dispenser (10) has a nozzle (12), an internal liquid conduit, a valve (11) and a body portion (30) and the detector (14) is located in or on the nozzle, between the nozzle and body portion or in the body portion.
12. A method according to claim 11 wherein the vapour is drawn through the nozzle (12) to the detector (14) located in the line of an automatic cut out mechanism (33, 34, 35, 47) controlling the operation of said valve.
13. A method according to claim 11 or 12 wherein the vapour passes the detector (14) located in an annular chamber (40) surrounding at least part of said nozzle (12) or liquid conduit.
14. A method according to claim 13 wherein the chamber also comprises a processor (22) to analyze the results from the detector (14) and controller (23) to act on instructions from said processor.
15. A method according to claim 10 wherein the vapour is drawn past a detector (14) located in a sheath (72) surrounding at least part of said dispenser.
16. A method according to claim 9 wherein the detector is associated with the tank (16) providing the second location.
17. A method according to claim 16 wherein the detector (14) and releasable closure means are located in a neck to said tank.
18. A method according to any one of claims 10-16 wherein said releasable closure means (11) is located in said dispenser (10).
19. A method according to any one of claims 10-16 wherein said releasable closure means is located in a body upstream of said dispenser in said liquid line.
20. A method according to any one of the preceding claims wherein the detector is a solid state gas sensor.
21. An apparatus for allowing controllable passage of a liquid which comprises a first zone (1) for containing said liquid and optionally a vapour space thereabove, a reversible closure means (7, 11), a first line (5) between said first zone and said closure means, a second zone (16) defining a vapour space, a second line (9) from said closure means to or into said second zone, at least one detector (14) for analyzing vapour in or from said second zone or above liquid in said first zone, transmission means (20, 21), processing means (22) and means (23) for controlling movement of said closure means, said transmission means being for transmitting the data from said detector(s) to said processing means for comparing said data from one of said zones with a pre-set level or with data from

the other of said zones, and operation of said processing means and controlling means being dependant on said comparison.

22. An apparatus according to claim 21 wherein said first zone has a vapour space thereabove.
23. An apparatus according to claim 21 or 22 wherein the detector is mounted on the second line (9) and is associated with a liquid dispenser (10) as defined in any one of claims 10-15 and 18.
24. An apparatus for dispensing a liquid which comprises a liquid dispenser (10) having a nozzle (12) for inserting into a tank (16) containing vapour, a liquid feed line (60) through said apparatus, a first reversible closure means (11) in said dispenser or in said liquid feed line for control of dispensing said liquid, a detector (14) for contacting the vapour from or in the tank, first means (20) for passing a signal from said detector to a processing means (22) for comparison of said signal with a present value or with a signal from another vapour detector, and a controller (23), means (21) for passing a signal from said processing means to said controller which receives output from said comparison for controlling movement of the liquid.
25. An apparatus according to claim 24 wherein said controller (23) controls operation of said reversible closure means (11).
26. An apparatus according to claim 24 which comprises a separate housing for use upstream of said dispenser in said liquid feed line, a second valve in a partly flexible part of said feed line in said housing, operation of said second valve being controlled by said controller.
27. An apparatus according to any one of claims 24-26 which comprises a dispenser (10) comprising said nozzle (12), reversible closure means which is a first valve (11), and liquid feed line, and a separate housing for use upstream of said dispenser in said feed line, said housing comprising said processing means, second signal passage means, controlling means and a second valve controlling movement of said liquid.
28. An apparatus according to any one of claims 24-26 which is a liquid dispenser (10) which comprises a nozzle (12) for exit of the liquid, a conduit (60) through the dispenser for the liquid, a reversible closure means, which is a first valve (11) in said conduit (60) urged to a closed position by urging means but releasably openable against said urging means, a manually operable actuator (32) to open said first valve, a vapour detector (14) comprised by said dispenser (10) adapted to be in vapour contact with vapours at the exit end of said nozzle, means (20) for passing the output from said detector (14) to a data processor (22) and means (23) for controlling said first valve from the output of said processor.
29. An apparatus according to any one of claims 24-28 which comprises an automatic cut out mechanism for said reversible closure means which is a first valve (11), said mechanism comprising a narrow tube (33) from a dispensing end of the nozzle (12) to a head end of the nozzle, a conduit (34, 45) from said head end to a safety device (47) causing liquid cut out, said detector (14) being located in said conduit.
30. An apparatus according to claim 28 or 29 wherein said detector (14) is located in an annular chamber (48) surrounding at least part of said nozzle (12) or liquid conduit, said chamber being open to said hollow tube (33) or open to vapours outside said nozzle.
31. An apparatus according to claim 30 wherein said chamber also comprises said processor (22) and controller (23).
32. An apparatus according to any one of claims 24-28, which also comprises a sheath (72) surrounding at least part of the nozzle, said detector (14) being capable of being in vapour contact with vapour in said sheath.

#### Patentansprüche

1. Verfahren zum Steuern der Bewegung einer Flüssigkeit von einem ersten Ort (1) zu einem zweiten Ort (16) über eine Verschlusseinrichtung, die sich reversibel mindestens teilweise zwischen einer offenen und einer geschlossenen Stellung bewegen kann, wobei mindestens einer von dem ersten und zweiten Ort einen Dampfraum aufweist, welches Verfahren umfasst: Analysieren des Dampfes in einem oder beiden Orten, Vergleichen der Ergebnisse der Analyse(n) mit einem Standard oder miteinander, und Verwenden der Ergebnisse des Vergleichs, um

die Bewegung der Verschlusseinrichtung zu steuern.

2. Verfahren nach Anspruch 1, bei welchem der erste und zweite Ort einen Dampfraum aufweisen.
- 5 3. Verfahren nach Anspruch 1 oder 2, bei welchem die Flüssigkeit, die bewegt wird, nicht Benzin oder Leichtöl ist.
4. Verfahren nach einem der vorangehenden Ansprüche, bei welchem der erste Ort den Dampfraum oberhalb von der Flüssigkeit aufweist, der zweite Ort Dampfraum aufweist, wobei das Verfahren umfasst: Analysieren des Dampfs in oder aus dem zweiten Ort und fakultativ in oder aus dem ersten Ort, und Vergleichen der Ergebnisse der Analyse in oder aus dem zweiten Ort mit einem Standard oder mit den Ergebnissen aus der Analyse in oder aus dem ersten Ort.
- 10 5. Verfahren nach einem der vorangehenden Ansprüche, bei welchem die Flüssigkeit einen flüssigen Kohlenwasserstoff umfasst und mindestens einer von dem ersten und zweiten Ort einen Dampfraum oberhalb von einer Flüssigkeit aufweist.
- 15 6. Verfahren nach Anspruch 4 oder 5, bei welchem der Dampf in jedem von dem ersten und zweiten Ort unabhängig ausgewählt wird aus:
  - 20 (a) Flugzeugbenzin und Kerosin, oder
  - (b) Motorenbenzin und Dieselöl, oder
  - (c) verbleitem Benzin und unverbleitem Benzin.
- 25 7. Verfahren nach einem der vorangehenden Ansprüche, bei welchem die Analyse eine Analyse der Gesamtdampfkonzentration ist, und der Vergleich der Ergebnisse der Analyse die Bewegung der Verschlusseinrichtung in Abhängigkeit davon steuert, ob die Gesamtdampfkonzentration oberhalb oder unterhalb eines definierten Pegels liegt.
- 30 8. Verfahren nach einem der Ansprüche 1-6, bei welchem die Analyse für mindestens eine in der Flüssigkeit vorhandene Verbindung spezifisch ist, und der Vergleich der Ergebnisse der Analyse die Bewegung der Verschlusseinrichtung in Abhängigkeit davon steuert, ob die Menge der vorhandenen Verbindung(en) oberhalb oder unterhalb eines definierten Pegels liegt.
- 35 9. Verfahren nach einem der vorangehenden Ansprüche, bei welchem der erste Ort ein ortsfester Flüssigkeitstank (1) ist, und der zweite Ort ein Tank (16) eines beweglichen Fahrzeugs ist.
- 40 10. Verfahren nach Anspruch 9, welches umfasst: Analysieren des Dampfs im zweiten Ort (16), indem man ihn an einem Detektor (14) vorbei abzieht, der mit einer Abgabevorrichtung (10) für die Flüssigkeit verbunden ist, die ein freigebares Ventil (11) umfasst, wobei sich die Abgabevorrichtung in einer Flüssigkeitsleitung (5, 9) zwischen dem ersten und zweiten Ort befindet.
- 45 11. Verfahren nach Anspruch 10, bei welchem die Abgabevorrichtung (10) einen Einfüllstutzen (12), einen inneren Flüssigkeitskanal, ein Ventil (11) und einen Körperteil (30) aufweist, und der Detektor (14) in oder auf dem Einfüllstutzen, zwischen dem Einfüllstutzen und dem Körperteil oder im Körperteil angeordnet ist.
12. Verfahren nach Anspruch 11, bei welchem der Dampf durch den Einfüllstutzen (12) zum Detektor (14) gesaugt wird, der in der Leitung eines automatischen Abstellmechanismus (33, 34, 35, 47) angeordnet ist, der die Betätigung des Ventils steuert.
- 50 13. Verfahren nach Anspruch 11 oder 12, bei welchem der Dampf den Detektor (14) passiert, der in einer ringförmigen Kammer (40) angeordnet ist, die mindestens einen Teil des Einfüllstutzens (12) oder des Flüssigkeitskanals umgibt.
- 55 14. Verfahren nach Anspruch 13, bei welchem die Kammer auch einen Rechner oder Prozessor (22) umfasst, um die Ergebnisse aus dem Detektor (14) zu analysieren, sowie eine Steuerung (23), um auf Befehle vom Rechner oder Prozessor hin zu handeln.
15. Verfahren nach Anspruch 10, bei welchem der Dampf an einem Detektor (14) vorbei gesaugt wird, der in einer Umhüllung (72) angeordnet ist, die mindestens einen Teil der Abgabevorrichtung umgibt.

16. Verfahren nach Anspruch 9, bei welchem der Detektor mit dem Tank (16) verbunden ist, der den zweiten Ort liefert.
17. Verfahren nach Anspruch 16, bei welchem der Detektor (14) und die freigebbare Verschlusseinrichtung in einem Hals zu dem Tank angeordnet sind.
18. Verfahren nach einem der Ansprüche 10-16, bei welchem die freigebbare Verschlusseinrichtung (11) in der Abgabevorrichtung (10) angeordnet ist.
19. Verfahren nach einem der Ansprüche 10-16, bei welchem die freigebbare Verschlusseinrichtung in einem Körper in Strömungsrichtung vor der Abgabevorrichtung in der Flüssigkeitsleitung angeordnet ist.
20. Verfahren nach einem der vorangehenden Ansprüche, bei welchem der Detektor ein Festkörper-Gassensor ist.
21. Vorrichtung zum Gestatten eines steuerbaren Durchflusses einer Flüssigkeit, welche umfasst: eine erste Zone (1) zum Enthalten der Flüssigkeit und fakultativ einen Dampfraum darüber, eine reversible Verschlusseinrichtung (7, 11), eine erste Leitung (5) zwischen der ersten Zone und der Verschlusseinrichtung, eine zweite Zone (16), die einen Dampfraum begrenzt, eine zweite Leitung (9) von der Verschlusseinrichtung zu der zweiten Zone oder in die zweite Zone, mindestens einen Detektor (14) zum Analysieren von Dampf in oder aus der zweiten Zone oder oberhalb von Flüssigkeit in der ersten Zone, eine Übertragungseinrichtung (20, 21), eine Verarbeitungseinrichtung (22) und eine Einrichtung (23) zum Steuern einer Bewegung der Verschlusseinrichtung, wobei die Übertragungseinrichtung zum Übermitteln der Daten von dem (den) Detektor(en) zur Verarbeitungseinrichtung dient, um die Daten aus einer der Zonen mit einem voreingestellten Pegel oder mit Daten aus der anderen der Zonen zu vergleichen, und eine Tätigkeit der Verarbeitungseinrichtung und der Steuereinrichtung von dem Vergleich abhängig ist.
22. Vorrichtung nach Anspruch 21, bei welcher die erste Zone einen Dampfraum darüber aufweist.
23. Vorrichtung nach Anspruch 21 oder 22, bei welcher der Detektor auf der zweiten Leitung (9) angebracht ist und mit einer Flüssigkeitsabgabevorrichtung (10), wie in einem der Ansprüche 10-15 und 18 definiert, verbunden ist.
24. Vorrichtung zum Abgeben einer Flüssigkeit, welche umfasst: eine Flüssigkeitsabgabevorrichtung (10) mit einem Einfüllstutzen (12) zum Einführen in einen Dampf enthaltenden Tank (16), eine Flüssigkeitszufuhrleitung (16) durch die Vorrichtung, eine erste reversible Verschlusseinrichtung (11) in der Abgabevorrichtung oder in der Flüssigkeitszufuhrleitung zum Steuern der Abgabe der Flüssigkeit, einen Detektor (14), um mit Dampf aus dem oder in dem Tank in Kontakt zu treten, eine erste Einrichtung (20) zum Leiten eines Signals vom Detektor zu einer Verarbeitungseinrichtung (22) zum Vergleich des Signals mit einem voreingestellten Wert oder mit einem Signal von einem anderen Dampfdetektor, und eine Steuerung (23), Einrichtungen (21) zum Leiten eines Signals von der Verarbeitungseinrichtung zur Steuerung, die eine Ausgangsgröße aus dem Vergleich zum Steuern der Bewegung der Flüssigkeit erhält.
25. Vorrichtung nach Anspruch 24, bei welcher die Steuerung (23) die Betätigung der reversiblen Verschlusseinrichtung (11) steuert.
26. Vorrichtung nach Anspruch 24, welche umfasst: ein separates Gehäuse zur Verwendung in Strömungsrichtung vor der Abgabevorrichtung in der Flüssigkeitszufuhrleitung, ein zweites Ventil in einem teilweise flexiblen Teil der Zufuhrleitung in dem Gehäuse, wobei eine Betätigung des zweiten Ventils durch die Steuerung gesteuert wird.
27. Vorrichtung nach einem der Ansprüche 24-26, welche umfasst: eine Abgabevorrichtung (10), umfassend den Einfüllstutzen (12), eine reversible Verschlusseinrichtung, die ein erstes Ventil (11) ist, und eine Flüssigkeitszufuhrleitung, und ein separates Gehäuse zur Verwendung in Strömungsrichtung vor der Abgabevorrichtung in der Zufuhrleitung, wobei das Gehäuse die Verarbeitungseinrichtung, die zweite Signalleitungseinrichtung, die Steuereinrichtung und ein zweites Ventil umfasst, das die Bewegung der Flüssigkeit steuert.
28. Vorrichtung nach einem der Ansprüche 24-26, welche eine Flüssigkeitsabgabevorrichtung ist, die umfasst: einen Einfüllstutzen (12) für den Austritt der Flüssigkeit, einen Kanal (60) durch die Abgabevorrichtung für die Flüssigkeit, eine reversible Verschlusseinrichtung, die ein erstes Ventil (11) in dem Kanal (60) ist, das durch eine Zwangseinrichtung in eine geschlossene Stellung gezwungen wird, sich jedoch entgegen der Zwangseinrichtung freigebbar öffnen lässt, ein von Hand bedienbares Betätigungsglied (32) zum Öffnen des ersten Ventils, einen von der Ab-

gabevorrichtung (10) umfassten Dampfdetektor (14), der angepasst ist, um sich im Dampfkontakt mit Dämpfen am Austrittsende des Einfüllstutzens zu befinden, eine Einrichtung (20) zum Leiten der Ausgangsgröße aus dem Detektor (14) zu einer Datenverarbeitungseinrichtung (22) oder einem Datenprozessor, und eine Einrichtung (23) zum Steuern des ersten Ventils aus der Ausgangsgröße des Prozessors.

29. Vorrichtung nach einem der Ansprüche 24-28, welche umfasst: einen automatischen Abstellmechanismus für die reversible Verschlusseinrichtung, die ein erstes Ventil (11) ist, wobei der Mechanismus umfasst: ein enges Rohr (33) von einem Abgabeende des Einfüllstutzens (12) bis zu einem Kopfende des Einfüllstutzens, einen Kanal (34, 45) vom Kopfende bis zu einer Sicherheitsvorrichtung (47), die ein Abstellen der Flüssigkeit bewirkt, wobei der Detektor (14) in der Leitung angeordnet ist.

30. Vorrichtung nach Anspruch 28 oder 29, bei welcher der Detektor (14) in einer ringförmigen Kammer (48) angeordnet ist, die mindestens einen Teil des Einfüllstutzens (12) oder des Flüssigkeitskanals umgibt, wobei die Kammer zum hohlen Rohr (31) hin offen ist oder für Dämpfe außerhalb des Einfüllstutzens offen ist.

31. Vorrichtung nach Anspruch 30, bei welcher die Kammer auch den Prozessor (22) und die Steuerung (23) umfasst.

32. Vorrichtung nach einem der Ansprüche 24-28, welche auch eine Umhüllung (72) umfasst, die mindestens einen Teil des Einfüllstutzens umgibt, wobei sich der Detektor (14) in Dampfkontakt mit Dampf in der Umhüllung befinden kann.

#### Revendications

1. Procédé pour commander le mouvement d'un liquide, d'un premier emplacement (1) vers un second emplacement (16) par l'intermédiaire de moyens de fermeture susceptibles de passer de manière réversible, au moins partiellement, d'une position ouverte à une position fermée, au moins un des premier et second emplacements ayant un espace de vapeur, lequel procédé comprend l'analyse de la vapeur dans un ou les deux emplacements, la comparaison des résultats de la ou des analyses avec une valeur de référence ou l'une avec l'autre et l'utilisation des résultats découlant de la comparaison pour commander le mouvement des moyens de fermeture.

2. Procédé selon la revendication 1, dans lequel les premier et second emplacements ont un espace de vapeur.

3. Procédé selon la revendication 1 ou 2, dans lequel le liquide qui est déplacé n'est pas de l'essence ou du pétrole léger.

4. Procédé selon l'une quelconque des revendications précédentes, dans lequel le premier emplacement a l'espace de vapeur au-dessus du liquide, le second emplacement a de l'espace de vapeur, le procédé comprenant l'analyse de la vapeur dans ou à partir du second emplacement et facultativement, dans ou à partir du premier emplacement, et la comparaison des résultats de l'analyse dans ou à partir du second emplacement avec une valeur de référence ou avec les résultats découlant de l'analyse effectuée dans ou à partir du premier emplacement.

5. Procédé selon l'une quelconque des revendications précédentes, dans lequel le liquide comprend un hydrocarbure liquide, et au moins un desdits premier et second emplacements a un espace de vapeur au-dessus d'un liquide.

6. Procédé selon la revendication 4 ou 5, dans lequel la vapeur dans chacun des premier et second emplacements est choisie indépendamment à partir de :

- (a) essence aviation et kérosène, ou
- (b) carburant moteur et carburant diesel ou
- (c) essence au plomb et essence sans plomb.

7. Procédé selon l'une quelconque des revendications précédentes, dans lequel l'analyse est celle de la concentration de vapeur totale et la comparaison des résultats de l'analyse commande le mouvement des moyens de fermeture selon que la concentration de vapeur totale se situe au-dessus ou au-dessous d'un niveau défini.

8. Procédé selon l'une quelconque des revendications 1 à 6, dans lequel l'analyse est spécifique à au moins un composé présent dans ledit liquide et la comparaison des résultats de l'analyse commande le mouvement des

moyens de fermeture selon que la quantité dudit/desdits composant(s) présent(s) se situe au-dessus ou au-dessous d'un niveau défini.

- 5 9. Procédé selon l'une quelconque des revendications précédentes, dans lequel le premier emplacement est un réservoir fixe (1) de liquide et le second emplacement est un réservoir (16) d'un véhicule mobile.
- 10 10. Procédé selon la revendication 9, qui comprend l'analyse de la vapeur dans le second emplacement (16) en l'amenant à passer devant un détecteur (14) associé à un pistolet distributeur (10), destiné au liquide, comprenant un clapet amovible (11), ledit pistolet distributeur étant un tuyau à liquide (5, 9) entre les premier et second emplacements.
- 15 11. Procédé selon la revendication 10, dans lequel le pistolet distributeur (10) possède une buse (12), un conduit à liquide intérieur, un clapet (11) et une partie formant corps (30) et le détecteur (14) est placé dans ou sur la buse, entre la buse et la partie formant corps ou dans la partie formant corps.
- 20 12. Procédé selon la revendication 11, dans lequel la vapeur est tirée à travers la buse (12) jusqu'au détecteur (14) situé dans la conduite d'un mécanisme d'interruption automatique (33, 34, 35, 47) commandant le fonctionnement dudit clapet.
- 25 13. Procédé selon la revendication 11 ou 12, dans lequel la vapeur passe devant le détecteur (14) situé dans une chambre annulaire (40) entourant au moins une partie de ladite buse (12) ou dudit conduit à liquide.
14. Procédé selon la revendication 13, dans lequel la chambre comprend également un système de traitement (22) pour analyser les résultats provenant du détecteur (14) et du dispositif de commande (23) pour agir sur les instructions délivrées par ledit système de traitement.
- 30 15. Procédé selon la revendication 10, dans lequel la vapeur est amenée à passer devant un détecteur (14) situé dans une gaine (72) entourant au moins une partie dudit pistolet distributeur.
- 35 16. Procédé selon la revendication 9, dans lequel le détecteur est associé au réservoir (16) fournissant le second emplacement.
17. Procédé selon la revendication 16, dans lequel le détecteur (14) et les moyens de fermeture amovibles sont situés dans un col sur ledit réservoir.
- 40 18. Procédé selon l'une quelconque des revendications 10 à 16, dans lequel lesdits moyens de fermeture amovibles (11) sont situés dans ledit pistolet distributeur (10).
19. Procédé selon l'une quelconque des revendications 10 à 16, dans lequel lesdits moyens de fermeture amovibles sont situés dans un corps en amont dudit pistolet distributeur dans ledit tuyau à liquide.
- 45 20. Procédé selon l'une quelconque des revendications précédentes, dans lequel le capteur est un capteur de gaz à l'état solide.
- 50 21. Appareil destiné à permettre le passage pouvant être commandé d'un liquide qui comprend une première zone (1) destinée à contenir ledit liquide et facultativement un espace de vapeur au-dessus de celui-ci, des moyens de fermeture réversibles (7, 11), un premier tuyau (5) entre ladite première zone et lesdits moyens de fermeture, une seconde zone (16) définissant un espace de vapeur, un second tuyau (9) partant desdits moyens de fermeture vers ou dans ladite seconde zone, au moins un détecteur (14) destiné à analyser la vapeur dans ou à partir de ladite seconde zone ou au-dessus du liquide dans ladite première zone, des moyens de transmission (20, 21), des moyens de traitement (22) et des moyens (23) pour commander le mouvement desdits moyens de fermeture, lesdits moyens de transmission étant destinés à transmettre les données dudit/desdits détecteur(s) auxdits moyens de traitement pour comparer lesdites données provenant d'une desdites zones avec un niveau prédéterminé ou avec les données provenant de l'autre desdites zones, et le fonctionnement desdits moyens de traitement et desdits moyens de commande dépendant de ladite comparaison.
- 55 22. Appareil selon la revendication 21, dans lequel ladite première zone a un espace de vapeur au-dessus.

23. Appareil selon la revendication 21 ou 22, dans lequel le détecteur est monté sur le second tuyau (9) et est associé à un pistolet distributeur (10) selon l'une quelconque des revendications 10 à 15 et 18.
- 5 24. Appareil pour distribuer un liquide qui comprend un pistolet distributeur de liquide (10) ayant une buse (12) destinée à être insérée dans un réservoir (16) contenant de la vapeur, un tuyau d'alimentation en liquide (60) traversant ledit appareil, des premiers moyens de fermeture réversibles (11) dans ledit pistolet distributeur ou dans ledit tuyau d'alimentation en liquide pour commander la distribution dudit liquide, un détecteur (14) pour venir en contact avec la vapeur provenant de ou présente dans le réservoir, des premiers moyens (20) destinés à transmettre un signal dudit détecteur à des moyens de traitement (22) afin de comparer ledit signal avec une valeur présente ou avec  
10 un signal provenant d'un autre détecteur de vapeur, et un dispositif de commande (23), des moyens (21) pour transmettre un message desdits moyens de traitement vers ledit dispositif de commande qui reçoit la sortie découlant de ladite comparaison afin de commander le mouvement du liquide.
- 15 25. Appareil selon la revendication 24, dans lequel ledit dispositif de commande (23) commande le fonctionnement desdits moyens de fermeture réversibles (11).
26. Appareil selon la revendication 24, qui comprend un boîtier distinct destiné à être utilisé en amont dudit pistolet distributeur dans ledit tuyau d'alimentation en liquide, un second clapet dans une partie partiellement flexible dudit tuyau d'alimentation dans ledit boîtier, le fonctionnement dudit second clapet étant commandé par ledit dispositif  
20 de commande.
27. Appareil selon l'une quelconque des revendications 24 à 26 qui comprend un pistolet distributeur (10) comprenant ladite buse (12), des moyens de fermeture réversibles qui sont un premier clapet (11), et un tuyau d'alimentation en liquide, et un boîtier distinct destiné à être utilisé en amont dudit pistolet distributeur dans ledit tuyau d'alimen-  
25 tation, ledit boîtier comprenant lesdits moyens de traitement, des seconds moyens de transmission de signaux, des moyens de commande et un second clapet commandant le mouvement dudit liquide.
28. Appareil selon l'une quelconque des revendications 24 à 26, qui est un pistolet distributeur de liquide (10) comprenant une buse (12) destinée à faire sortir le liquide, un conduit (60) traversant le pistolet distributeur pour le  
30 liquide, des moyens de fermeture réversibles qui sont un premier clapet (11) dans ledit conduit (60) sollicité par des moyens de sollicitation pour venir dans une position fermée, mais susceptible de s'ouvrir de manière amovible à l'encontre desdits moyens de sollicitation, un dispositif d'actionnement pouvant fonctionner manuellement (32) pour ouvrir ledit premier clapet, un détecteur de vapeur (14) se composant dudit pistolet distributeur (10) adapté pour être en contact avec les vapeurs au niveau de l'extrémité de sortie de ladite buse, des moyens (20) pour  
35 transmettre les données de sortie depuis ledit détecteur (14) jusqu'à un système de traitement de données (22) et des moyens (23) pour commander ledit premier clapet à partir de la sortie dudit système de traitement.
29. Appareil selon l'une quelconque des revendications 24 à 28 qui comprend un mécanisme d'interruption automatique pour lesdits moyens de fermeture réversibles qui sont un premier clapet (11), ledit mécanisme comprenant  
40 un tube étroit (33) partant d'une extrémité distributrice de la buse (12) jusqu'à une extrémité de tête de la buse, un conduit (34, 35) partant de ladite extrémité de tête jusqu'à un dispositif de sécurité (47) entraînant l'interruption de l'écoulement du liquide, ledit détecteur (14) étant situé dans ledit conduit.
30. Appareil selon la revendication 28 ou 29, dans lequel ledit détecteur (14) est situé dans une chambre annulaire (48) entourant au moins une partie de ladite buse (12) ou du conduit à liquide, ladite chambre étant ouverte audit  
45 tube creux (33) ou ouverte aux vapeurs à l'extérieur de ladite buse.
31. Appareil selon la revendication 30, dans lequel ladite chambre comprend également ledit système de traitement (22) et le dispositif de commande (23).  
50
32. Appareil selon l'une quelconque des revendications 24 à 28, qui comprend également une gaine (72) entourant au moins une partie de la buse, ledit détecteur (14) étant susceptible de venir en contact avec la vapeur présente dans ladite gaine.
